Introduction

The purpose of this lab is to better understand the input/output ability of a processor. The two methods being used in the lab are program-controlled polling I/O technique and interrupt-driven approach. A parallel port interface will be used on the Altera DE series board. The first part of the lab asks to use LEDs within the program to display the accumulated sum. The second part of the lab task asks for a push button to be added to a program for users to press when they want to read a new number into a program that reads numbers continuously. The third part asks to modify a given code to display a sum as a hexadecimal number in the display.

Part 1

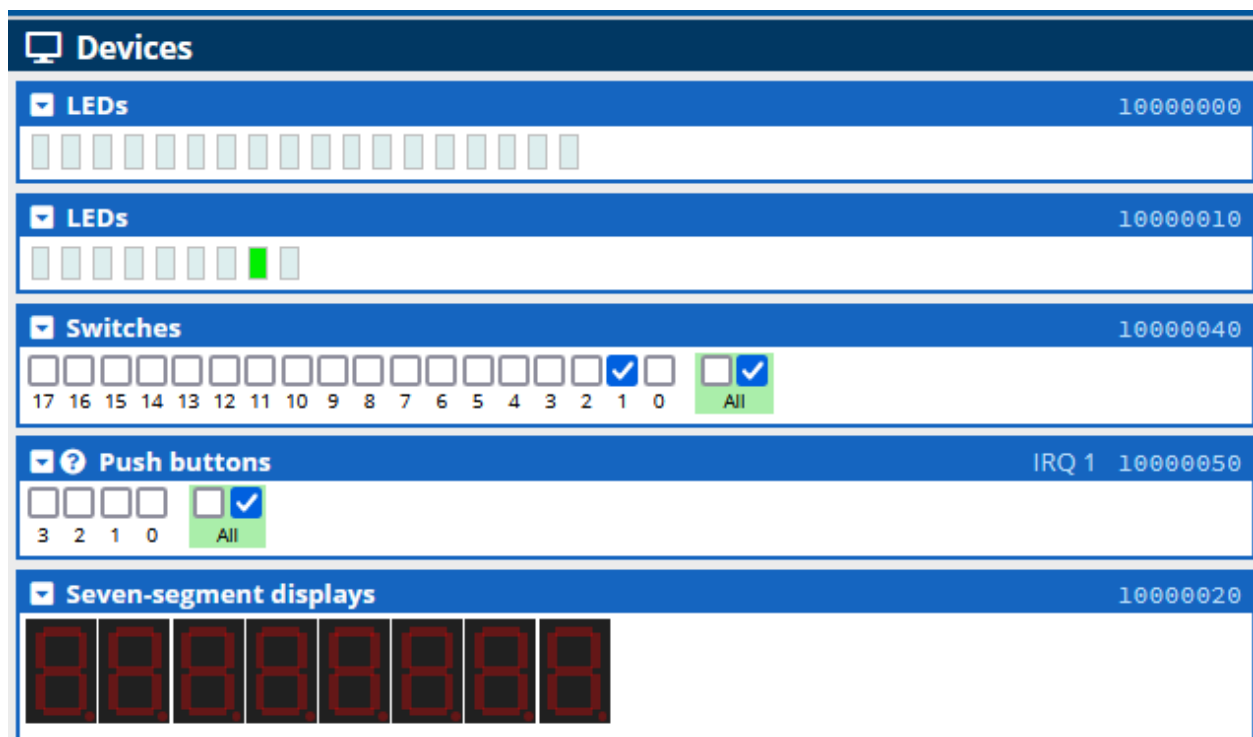

Figure 1: After clicking on switch 1 and stepping into multiple times, LED lights up in position 2.

Figure 16: Compilation successful

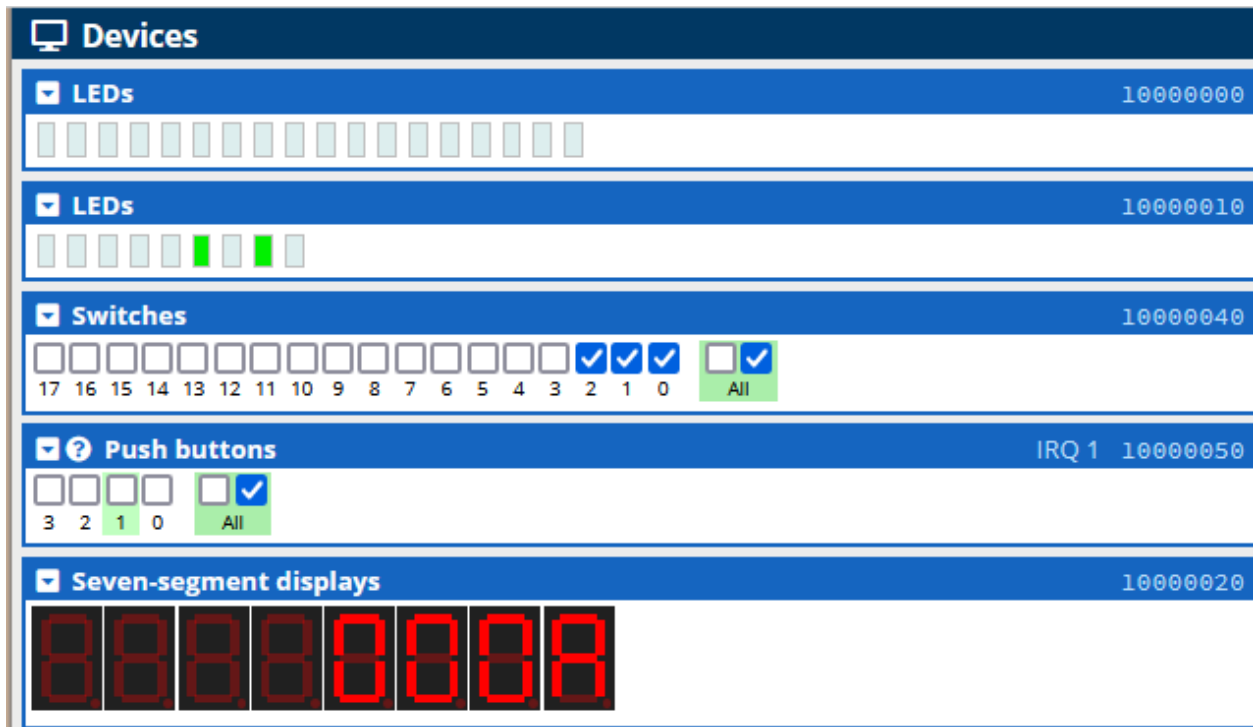

Figure 19: Selecting a different value and calculated a sum

Deliverables:

1. In part 1, is the “new number” read from memory? If not, where does it read from?

No, the number is read from the switches. The new number is sent to the processor using the input switches. These are connected through parallel ports and connected directly to register 16.

2. In part 2, how to modify the source code so the Key2 can be utilized?

Instead of using the line *andi r18, r18, 0x2* we would use *andi r18, r18, 0x4*

3. How many registers does the PIO interface contain? What are they?

The PIO interface contains 4 registers. They are the data, direction, interrupt-mask and edge capture registers.

4. In part 3, which register is used in the IO polling? Which line of code is used?

R8 is used to store the address of the data to retrieve. R10 holds the address of pushbutton, 3 registers further used for Edge-Capture/status register, These values are stored in r16 and r 18 respectively to check for further behavior.

Code:

```
ldwio r16, 0(r8)
ldwio r18, 12(r10)
```

5. In part 4, describe the interrupt method in your own words.

The interrupt method disrupts the normal execution of a program and causes the execution of special instructions. When the interrupt occurs, the microcontroller saves whatever it is currently doing and executes corresponding ISR code.

Conclusion

The lab was a success as all lab sections were completed successfully, and the group's understanding of polling input and output devices with a program controlled method and an interrupt driven input and output management method was enhanced. Furthermore, the group also learned more about Programming Input Output (PIO) Interfaces that is composed of four different registers; Data, Direction, Interrupt-mask, and Edge-capture register. The registers were used in different ways throughout each part of the lab to display the sums on the LED and seven segment display. The parallel port interfaces were used to accomplish these tasks.

Thus, this lab demonstrated fundamental and important topics of computer architecture and contributed to the improvement of the group's understanding of input and output mechanisms in the computer.
